Definition of Terms Used In This Comparison

Info Ratio - Information ratio is a risk-adjusted performance indicator that measures the ratio of portfolio returns above the returns of a benchmark to the volatility of those returns.

Upside Capture - Upside Capture Ratio measures a manager's performance in up markets. An up market is defined as those periods (months or quarters) in which market return is greater than 0. In essence, it tells you what percentage of the up market was captured by the manager.

Downside Capture - Downside Capture Ratio measures a manager's performance in down markets. A down market is defined as those periods (months or quarters) in which market return is less than 0. In essence, it tells you what percentage of the down market was captured by the manager.

R-Squared - R-squared is a statistical measure that represents the proportion of the variance for a dependent variable that's explained by an independent variable or variables in a regression model. Whereas correlation explains the strength of the relationship between an independent and dependent variable, R-squared explains to what extent the variance of one variable explains the variance of the second variable. In investing, R-squared is generally interpreted as the percentage of a fund or security's movements that can be explained by movements in a benchmark index.

Standard Deviation - The standard deviation is a statistic that measures the dispersion of a dataset relative to its mean and is calculated as the square root of the variance. Standard deviation is a statistical measurement in finance that, when applied to the annual rate of return of an investment, sheds light on the historical volatility of that investment.

Downside Risk - Downside risk is an estimation of a security's potential to suffer a decline in value if the market conditions change, or the amount of loss that could be sustained as a result of the decline. Depending on the measure used, downside risk explains a worst-case scenario for an investment or indicates how much the investor stands to lose.

Beta - Beta is a measure of systematic risk with respect to a benchmark. Systematic risk is the tendency of the value of the fund and the value of the benchmark to move together.

Alpha - A measure of the difference between a portfolio's actual return and its expected performance, given its level of risk as measured by beta.

Sharpe Ratio - A risk-adjusted measure calculated by using standard deviation and excess return to determine reward per unit of risk. The higher the Sharpe ratio, the better the fund's historical risk-adjusted performance.
